TITLE OF THE INVENTION

MEASURING APPARATUS AND MEASURING METHOD FOR PATTERN DEPENDENT JITTER

CROSS-REFERENCE TO RELATED APPLICATIONS

5 This application is based upon and claims the benefit of priority from the prior Japanese Patent Application No. 2002-365138, filed December 17, 2002, the entire contents of which are incorporated herein by reference.

10

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a measuring apparatus and a measuring method for pattern dependent jitter, and in particular, to a measuring apparatus and 15 a measuring method for pattern dependent jitter, in which a technique for measuring pattern dependent jitter which arises in dependence on a pattern of a data signal among jitter components included in the data signal.

20

2. Description of the Related Art

In a data transmission system, when fluctuation (jitter) in the phase of the data signal is large, the data signal cannot be normally transmitted.

Therefore, it is necessary to measure in advance 25 the jitter characteristics of the data transmission system and equipment configuring the system.

FIG. 10 shows a configuration of a conventional

10/736811

jitter measuring apparatus 10 used for such an object.

In FIG. 10, a clock generating unit 11 outputs a clock signal CK having a predetermined frequency, and a pattern generating unit 12 outputs a data signal Dt which is synchronized with the clock signal CK, and which has a predetermined pattern having a predetermined bit (N) length.

A measuring object 1 is, for example, a clock/data recovery circuit used for a data transmission system.

The clock/data recovery circuit serving as the measuring object 1 outputs the data signal Dt from the pattern generating unit 12, as a data signal Dr.

The data signal Dr outputted from the measuring object 1 is inputted to a waveform observing device 13 as a data signal to be measured.

The waveform observing device 13 displays waveform of the inputted data signal Dr to be measured as will be described later.

Namely, the waveform observing device 13 divides the clock signal CK by P (here, P is a number less than the data length N of the data signal Dt), and displays so as to overwrite waveform of the data signal Dr to be measured due to the level displacement timing of the divided signal being made to be the trigger timing.

At this time, when a pattern of the data signal Dt is random, for example, as shown in FIG. 11, waveform in which a rise and a fall intersect is displayed on

the waveform observing device 13.

This waveform is called eye-pattern, and when jitter in the data signal Dr to be measured is large, a width W of the intersection of the rise and the fall 5 of the eye-pattern is made large.

Accordingly, a jitter amount of the data signal Dr to be measured can be grasped in accordance with the width W of the intersection of the eye-pattern displayed on the waveform observing device 13.

10 Note that a method for determining jitter by observing the eye-pattern of a data signal as described above is described in, for example, Patent document 1 (Jpn. Pat. Appln. KOKAI Publication No. 5-145582).

15 However, in the method for measuring jitter based on the width W of the eye-pattern displayed on the waveform observing device 13 as described above, pattern dependent jitter which arises in dependence on a pattern of a data signal cannot be grasped.

20 Namely, as jitters, there are random noise jitter arising due to noise of equipment themselves, external noise, or the like, and pattern dependent jitter arising due to a pattern of a data signal which is transmitted.

25 The pattern dependent jitter is jitter arising due to waveform distortion generated because a DC component cannot pass through when a data transmission passing band of the measuring object 1 is high (several GHz),

duty cycle distortion of a data signal, waveform distortion generated because the frequency characteristic of the measuring object 1 is not sufficient for a frequency of the signal which is transmitted, or the like.

5 This pattern dependent jitter is not a serious problem when a data signal has strong random characteristic such as a pseudo-random pattern.

10 However, in a case where the data signal having the predetermined pattern is a data signal in which an unscrambled specific pattern always exists at the head position, such as a frame actually used for data transmission, for example, an SDH frame or a SONET frame, large pattern dependent jitter arises at the frame intervals (for example, 125 μs intervals).

15 Moreover, because the frequency of the pattern dependent jitter arising at this frame intervals is generally within a frequency band stipulated by jitter measurement, the pattern dependent jitter cannot be measured in distinction from other random noise jitter.

20 Further, in measurement of jitter in dependence on a pattern of a data signal as described above, it is necessary to exactly grasp the relation between the position of data and jitter.

25 However, it is difficult to exactly grasp the relation in the eye-pattern observation as described above.

Therefore, in the measurement of pattern dependent jitter, realization of a measuring apparatus for pattern dependent jitter and a jitter measuring method which can exactly grasp the relation between the position of data and jitter has been strongly desired.

BRIEF SUMMARY OF THE INVENTION

An object of the present invention is to provide a measuring apparatus and a measuring method for pattern dependent jitter which can exactly grasp the relation between the position of data and jitter in measurement of pattern dependent jitter.

In order to achieve the above object, according to a first aspect of the present invention, there is provided a pattern dependent jitter measuring apparatus comprising:

a clock generating unit which generates a clock signal having a predetermined frequency; and

20 a pattern generating unit which outputs a data signal having a predetermined pattern in which one frame is configured from a predetermined bit length, so as to be synchronized with the clock signal outputted from the clock signal generating unit, wherein the pattern dependent jitter measuring apparatus further comprises:

25 a waveform information acquiring unit which receives the data signal outputted from the pattern generating unit as a data signal to be measured, and

receives the clock signal outputted from the clock generating unit, and which acquires information of waveform in the same time domain of the data signal to be measured and the clock signal;

5 an averaging processing unit which carries out averaging processing on the waveform acquired by the waveform information acquiring unit;

10 a phase difference detecting unit determining the per-bit phase difference between the data signal to be measured and the clock signal, based on the waveform information averaged by the averaging processing unit;

15 a frequency band limiting processing unit which carries out predetermined frequency band limiting processing on information of the per-bit phase difference obtained by the phase difference detecting unit; and

20 a measured result outputting unit which outputs the phase difference information on which the frequency band limiting processing is carried out by the frequency band limiting processing unit, as pattern dependent jitter.

In order to achieve the above object, according to a second aspect of the present invention, there is provided a pattern dependent jitter measuring apparatus according to the first aspect, wherein the pattern generating unit is configured to include a data signal in which an unscrambled specific pattern exists at

a head position of each frame, as the data signal outputted from the pattern generating unit.

In order to achieve the above object, according to a third aspect of the present invention, there is
5 provided a pattern dependent jitter measuring apparatus according to the first aspect, wherein the waveform information acquiring unit is configured to receive a data signal to be outputted by a measuring object which has received the data signal outputted from the pattern generating unit, as the data signal to be measured, and receive a clock signal outputted from the clock generating unit, and acquire waveform information in the same time domain of the data signal to be measured and the clock signal.
10

15 In order to achieve the above object, according to a fourth aspect of the present invention, there is provided a pattern dependent jitter measuring apparatus according to the third aspect, wherein the measuring object includes equipment configured such that, when pattern dependent jitter is included in a data signal to be inputted, a pattern dependent jitter component included in the inputted data signal can be removed by waveform shaping processing at the inside thereof, and a data signal including random noise jitter and pattern dependent jitter which the measuring object itself
20 internally generates is outputted to the waveform information acquiring unit as the data signal to be
25

measured.

In order to achieve the above object, according to
a fifth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the first aspect, wherein the pattern
generating unit is configured to output a frame
synchronization signal synchronized with data output
timing at an arbitrary bit position in one frame of the
data signal, to the waveform information acquiring
unit, and

the waveform information acquiring unit is
configured to acquire a predetermined number of frames
of the waveform information of the data signal to be
measured and the clock signal by using the timing when
the frame synchronization signal is inputted as
a standard timing.

In order to achieve the above object, according to
a sixth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the fifth aspect, wherein the averaging
processing unit is configured to determine one frame of
waveform information of the clock signal and the data
signal to be measured from each of which the random
noise jitter component has been removed, by averaging
the predetermined number of frames of waveform
information which are acquired by the waveform
information acquiring unit.

In order to achieve the above object, according to
a seventh aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the sixth aspect, wherein the phase
difference detecting unit is configured such that a
phase difference (time difference) $\Delta T(i)$ between level
displacement timing of the clock signal which is
determined by the averaging processing unit, and from
which the random noise jitter component has been
removed, and a code boundary of the data signal to be
measured, is determined for each bit, and such that
per-bit phase difference $\Delta T(i)'$ is determined by

$$\Delta T(1)' = 0, \text{ and}$$

$$\Delta T(i)' = \Delta T(i) - \Delta T(1) \quad (i = 2, 3, \dots, N),$$

by correcting the phase differences $\Delta T(2)$, $\Delta T(3)$, ...
 $\Delta T(N)$ from the second bit on by the bit difference
 $\Delta T(1)$ of the first bit.

In order to achieve the above object, according to
an eighth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the seventh aspect, wherein the phase
difference detecting unit is configured such that
detection of the level displacement timing is carried
out after it is judged whether or not an amplitude of
the data signal to be measured that is determined by
the averaging processing unit exceeds a threshold
value.

In order to achieve the above object, according to
a ninth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the seventh aspect, wherein the phase
difference detecting unit detects timing only when a
5 code of the data signal to be measured determined by
the averaging processing unit is changed, with respect
to the detection of level displacement timing, and
determines a time difference between the timing and the
10 level displacement timing of the clock signal as a
phase difference.

In order to achieve the above object, according to
a tenth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the seventh aspect, wherein the phase
difference detecting unit is configured such that, when
15 the code of the data signal to be measured determined
by the averaging processing unit is not changed, with
respect to the detection of level displacement timing,
the phase difference of the previous bit is allocated.
20

In order to achieve the above object, according to
an eleventh aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the first aspect, wherein the frequency
band limiting processing unit is configured to include
25 a digital filter formed by digital signal processing
means.

In order to achieve the above object, according to
a twelfth aspect of the present invention, there is
provided a pattern dependent jitter measuring apparatus
according to the first aspect, wherein the waveform
5 information acquiring unit and the averaging processing
unit are configured from a sampling oscilloscope.

In order to achieve the above object, according to
a thirteenth aspect of the present invention, there is
provided a pattern dependent jitter measuring method
10 comprising:

15 outputting a data signal which is synchronized
with a clock signal having a predetermined frequency,
and has a predetermined pattern of a predetermined bit
length, wherein the pattern dependent jitter measuring
method further comprises:

20 receiving the data signal as a data signal to
be measured, and receiving the clock signal, thereby
to acquiring waveform information in the same time
domain of the data signal to be measured and the
clock signal;

carrying out averaging processing on the
waveform acquired by the acquiring of the waveform
information;

25 detecting phase differences of the data signal
to be measured and the clock signal, for each bit
of the data signal to be measured, based on
the waveform information obtained by the averaging

processing;

carrying out predetermined frequency band limiting processing on the phase difference information detected for each bit; and

5 outputting the phase difference information on which the predetermined frequency band limiting processing is carried out, as pattern dependent jitter.

In order to achieve the above object, according to
a fourteenth aspect of the present invention, there is
10 provided a pattern dependent jitter measuring method
according to the thirteenth aspect, wherein the
outputting of a data signal outputs a data signal in
which an unscrambled pattern exists at a head portion
of each frame, as the data signal.

15 In order to achieve the above object, according to
a fifteenth aspect of the present invention, there is
provided a pattern dependent jitter measuring method
according to the thirteenth aspect, wherein the method
further comprises:

20 inputting the data signal which is synchronized
with a clock signal having a predetermined frequency,
and which has a predetermined pattern of a
predetermined bit length, to a measuring object, and

25 the acquiring of the waveform information receives
a data signal outputted from the measuring object which
has received the data signal, as the data signal to be
measured, and receives the clock signal, and carries

out the acquiring of the waveform information in the same time domain of the data signal to be measured and the clock signal.

In order to achieve the above object, according to
5 a sixteenth aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the fifteenth aspect, wherein the measuring object includes equipment configured such that, when the pattern dependent jitter is included in
10 a signal to be inputted, a pattern dependent jitter component included in the inputted data signal can be removed by waveform shaping processing at the inside thereof, and a data signal including random noise jitter and pattern dependent jitter which the measuring object itself internally generates, is outputted as the
15 data signal to be measured.

In order to achieve the above object, according to a seventeenth aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the thirteenth aspect, wherein the method further comprises:

20 outputting a frame synchronization signal synchronized with data output timing at an arbitrary bit position in one frame of the data signal, and
25 the acquiring of the waveform information acquires a predetermined number of frames of waveform information of the data signal to be measured and

the clock signal by using timing when the frame synchronization signal is inputted as a standard timing.

In order to achieve the above object, according to
5 an eighteenth aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the seventeenth aspect, wherein the averaging processing determines one frame of waveform information of the clock signal and the data signal to be measured from each of which the random noise jitter component has been removed, by averaging the predetermined number of frames of waveform information acquired by the acquisition of waveform information.
10
15

In order to achieve the above object, according to a nineteenth aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the eighteenth aspect, wherein the detecting of the phase difference detects a phase difference (time difference) $\Delta T(i)$ between level displacement timing of the clock signal which is determined by the averaging processing unit, and from which the random noise jitter component has been removed, and a code boundary of the data signal to be measured, for each bit, and determines per-bit phase difference $\Delta T(i)'$ by
20
25

$$\Delta T(1)' = 0, \text{ and}$$

$$\Delta T(i)' = \Delta T(i) - \Delta T(1) \quad (i = 2, 3, \dots, N),$$

by correcting phase differences $\Delta T(2)$, $\Delta T(3)$, ..., $\Delta T(N)$ from the second bit on by the bit difference $\Delta T(1)$ of the first bit.

In order to achieve the above object, according to
5 a twentieth aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the eighteenth aspect, wherein the detecting of the phase difference is configured such that detection of the level displacement timing is carried out after it is judged whether or not an 10 amplitude of the data signal to be measured determined by the averaging processing exceeds a threshold value.

In order to achieve the above object, according to a twenty-first aspect of the present invention, there 15 is provided a pattern dependent jitter measuring method according to the eighteenth aspect, wherein the detecting of the phase difference detects timing only when a code of the data signal to be measured determined by the averaging processing is changed, with respect to the detection of level displacement timing, 20 and determines a time difference between the timing and the level displacement timing of the clock signal as a phase difference.

In order to achieve the above object, according to 25 a twenty-second aspect of the present invention, there is provided a pattern dependent jitter measuring method according to the eighteenth aspect, wherein the

detecting of the phase difference is configured such
that, when the code of the data signal to be measured
determined by the equalization processing is not
changed, with respect to the detection of level
5 displacement timing, a phase difference of the previous
bit is allocated.

In order to achieve the above object, according to
a twenty-third aspect of the present invention, there
is provided a pattern dependent jitter measuring method
10 according to the thirteenth aspect, wherein the
acquiring of the waveform information and the averaging
processing are carried out by a sampling oscilloscope.

Additional objects and advantages of the invention
will be set forth in the description which follows, and
15 in part will be obvious from the description, or may be
learned by practice of the invention. The objects and
advantages of the invention may be realized and
obtained by means of the instrumentalities and
combinations particularly pointed out hereinafter.

20 BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The accompanying drawings, which are incorporated
in and constitute a part of the specification,
illustrate presently preferred embodiments of the
present invention and, together with the general
25 description given above and the detailed description of
the preferred embodiments given below, serve to explain
the principles of the invention.

FIG. 1 is a block diagram showing a configuration of a first embodiment of a jitter measuring apparatus according to the invention and a modified example thereof;

5 FIGS. 2A to 2F are timing charts shown for explanation of operations of the jitter measuring apparatus of FIG. 1;

10 FIG. 3 is a graph showing jitter waveform before frequency band limiting processing in the jitter measuring apparatus of FIG. 1;

FIG. 4 is a graph showing jitter waveform after frequency band limiting processing in the jitter measuring apparatus of FIG. 1;

15 FIG. 5 is a flowchart shown for explanation of measuring processing procedure of the jitter measuring apparatus of FIG. 1;

FIG. 6 is a block diagram showing a configuration of a second embodiment of a jitter measuring apparatus according to the invention;

20 FIGS. 7A to 7E are timing charts for explanation of operations of a main portion of the jitter measuring apparatus of FIG. 6;

25 FIG. 8 is a flowchart shown for explanation of measuring processing procedure of the jitter measuring apparatus of FIG. 6;

FIG. 9 is a block diagram showing a configuration of a third embodiment of a jitter measuring apparatus

according to the invention;

FIG. 10 is a block diagram showing a conventional jitter measuring system; and

5 FIG. 11 is a diagram for explanation of a conventional jitter measuring method.

DETAILED DESCRIPTION OF THE INVENTION

Reference will now be made in detail to the presently preferred embodiments of the invention as illustrated in the accompanying drawings, in which like 10 reference numerals designate like or corresponding parts.

Hereinafter, embodiments of the present invention will be described with reference to the drawings.

(First Embodiment)

15 FIG. 1 is a block diagram showing a basic configuration as a jitter measuring apparatus 20 according to a first embodiment to which the present invention is applied, and a modified example thereof.

20 In FIG. 1, a clock generating unit 21 outputs a clock signal CK having a predetermined frequency corresponding to a data transmission rate of a measuring object 1 (for example, about 2.5 Gbps or about 9.95 Gbps).

25 A pattern generating unit 22 repeatedly outputs a data signal Dt having a predetermined pattern in which one frame (for example, the SDH/SONET frame described above) is configured from a predetermined

bits N so as to synchronize with the clock signal CK.

In the case where the data signal Dt having the predetermined pattern is a data signal in which an unscrambled specific pattern always exists at 5 the head position, such as a frame actually used for data transmission, for example, an SDH frame or a SONET frame, large pattern dependent jitter arises at the frame intervals (for example, 125 µs intervals).

Further, the pattern generating unit 22 outputs 10 a frame synchronization signal S synchronizing with the data output timing at a predetermined bit position (for example, the head position) of the data signal Dt repeatedly outputted thereby.

Note that, here, the data signal Dt is an electric 15 signal. However, the data signal Dt may be an optical data signal as will be described later.

Further, the above-described clock generating unit 21 and pattern generating unit 22 can be configured from an integrated-type pattern generator 20 having the functions thereof.

A data signal outputted by such an integrated-type pattern generator may be any of an electric signal and an optical signal as described above.

The data signal Dt from the pattern generating 25 unit 22 is inputted to the measuring object 1 via an output terminal 20a.

The measuring object 1 is various types of

equipment used for a data transmission system, and here, the meaning object 1 will be described by using the case of a clock/data reproducer which waveform-shapes and outputs the data signal Dt in the same way
5 as in the above description.

A data signal Dr to be measured outputted from the measuring object 1 is inputted to a waveform information acquiring unit 23 via an input terminal 20b.

10 The waveform information acquiring unit 23 acquires plural (M) frames of waveform information (for example, M = 16) in the same time domain of the data signal Dr to be measured and the clock signal CK based on the input timing of the frame synchronization
15 signal S.

An averaging processing unit 24 carries out averaging processing on the degree M with respect to the waveform acquired by the waveform information acquiring unit 23.

20 Due to this averaging processing, the random noise jitter components included in the data signal Dr to be measured and the clock signal CK are eliminated, and only the components of pattern dependent jitters remain.

25 The waveform information acquiring unit 23 and the averaging processing unit 24 can be configured by using a digital sampling oscilloscope as will be

described later.

Based on the waveforms of the data signal Dr to be measured and the clock signal CK averaged by the averaging processing unit 24, a phase difference detecting unit 25 determines one frame (N bits) of the data signal Dr to be measured by using, as the unit of time, the phase difference, per bit, between the data signal Dr to be measured and the clock signal CK.

A frequency band limiting processing unit 26 carries out frequency band limiting processing which is determined in advance due to the above-described bit rate by using, for example, a DSP or the like, with respect to information of the phase difference for each bit detected by the phase difference detecting unit 25.

For example, in the case of the SDH/SONET described above, when a transmission rate is about 2.5 Gbps, the frequency band limiting processing of any of 5 kHz to 20 MHz, 12 kHz to 20 MHz, and 1 MHz to 20 MHz is carried out by the frequency band limiting processing unit 26.

Further, when a transmission rate is about 9.95 Gbps, the frequency band limiting processing of any of 20 kHz to 80 MHz, 50 kHz to 80 MHz, and 4 MHz to 80 MHz is carried out by the frequency band limiting processing unit 26.

A measured result outputting unit 27 is configured from a transmitter for carrying out transmission of

information to an indicator, a printer, or an external device, or the like, and the information of the phase differences to which frequency band limiting processing is applied by the frequency band limiting processing unit 26 is display-outputted, printed-out, or outputted to an external device, as a pattern dependent jitter Jdp which the measuring object 1 generates with respect to the data signal Dt.

Next, the operations of the jitter measuring apparatus 20 according to the first embodiment in this way will be described based on timing charts shown in FIGS. 2A to 2F.

With respect to the clock signal CK, as shown in FIG. 2B, which is outputted from the clock generating unit 21, the frame synchronization signal S and the data signal Dt (not showed, and for example, the SDH frame data described above) as shown in FIG. 2A are outputted from the pattern generating unit 22.

The data signal Dr to be measured as shown in FIG. 2C is outputted from the measuring object 1 which has received the data signal Dt.

Note that random noise jitters Jn are included in the clock signal CK, the data signal Dt, the data signal Dr to be measured, and the frame synchronization signal S.

Further, there are cases in which pattern dependent jitter is included in the data signal Dt

inputted to the measuring object 1. However, the component of the pattern dependent jitter included in the data signal Dt is eliminated due to the waveform shaping processing at the inside of the clock/data reproducer serving as the measuring object 1.

Accordingly, the random noise jitter and the pattern dependent jitter which the measuring object 1 itself (outputting portion) generates are included in the data signal Dr to be measured.

Such a data signal Dr to be measured is inputted to the waveform information acquiring unit 23 together with the clock signal CK outputted from the clock generating unit 21, and the waveform information (information regarding the amplitude values of each time) in the same time domain of the both signals are acquired.

Here, the waveform information acquiring unit 23 carries out, for example, processing in which the waveform information of the data signal Dr to be measured and the clock signal CK which are inputted during the time from the timing based on the timing when the frame synchronization signal S is inputted until the next frame synchronization signal S is inputted, are acquired, with respect to M frames thereof.

The averaging processing unit 24 determines one frame of waveform information (only a portion of which

is shown in FIGS. 2D and 2E) of the clock signal CK' and the data signal Dr' to be measured from each of which the random noise jitter component has been removed as shown in FIGS. 2D and 2E, by equalizing the 5 M frames of the waveform information acquired by the waveform information acquiring unit 23.

As shown in FIG. 2F, the phase difference detecting unit 25 determines a phase difference (time difference) $\Delta T(i)$ between the level displacement timing (here, fall edge) of the clock signal CK' from which the random noise jitter component has been removed and a code boundary of the data signal Dr' to be measured from which the random noise jitter component has been removed, for each bit, and a phase difference $\Delta T(i)'$ for each bit is determined as follows by correcting the phase differences $\Delta T(2)$, $\Delta T(3)$, ..., $\Delta T(N)$ from the second bit on by the bit difference $\Delta T(1)$ of the first bit.

$$\Delta T(1)' = 0$$

$$20 \quad \Delta T(i)' = \Delta T(i) - \Delta T(1) \quad (i = 2, 3, \dots, N)$$

Note that detection of each timing is carried out after it is judged whether or not a signal amplitude exceeds a threshold value. However, when the code of the data signal Dr' to be measured does not vary (the same code continues), it is difficult to detect the timing of the code boundary from the waveform.

Then, actually, only when the code of the data

signal Dr' to be measured varies, the timing is detected, and a time difference between the timing and the level displacement timing of the clock signal CK' is determined as a phase difference.

5 Furthermore, when the code of the data signal Dr' to be measured does not vary, a phase difference of the previous bit is allocated thereto.

10 The information of the phase differences $\Delta T(1)'$, $\Delta T(2)'$, ..., $\Delta T(N)'$ for one frame obtained in this way are generated due to the pattern dependent jitter, and when one frame of pattern dependent jitter is determined, for example, jitter waveform such as shown 15 in FIG. 3 is obtained.

For example, frequency band limiting processing of 20 4 MHz to 80 MHz corresponding to a bit rate of about 9.95 Gbps is carried out with respect to the jitter waveform by the frequency band limiting processing unit 26, jitter waveform such as shown in FIG. 4 is obtained.

25 The jitter waveform due to this frequency band limiting processing has been obtained by converting the jitter waveform for each bit of FIG. 3 into jitter waveform on the time base based on a bit rate, and by carrying out the above-described frequency band limiting by a digital filter.

It can be understood that large pattern dependent jitter arises at the head portion of the jitter

waveform due to an unscrambled specific pattern at the head portion of the SDH/SONET frame.

As shown in FIG. 4, the measured result outputting unit 27 displays the waveform of the jitter on which the frequency band limiting processing has been carried out, on a screen as the pattern dependent jitter which the measuring object 1 generates with respect to the data signal Dr, prints it out, or transmits it to another device.

Note that, other than being expressed by using the phase difference as the unit of time as described above, the measured results may be converted into UIpp (unit interval) units and outputted.

FIG. 5 is a flowchart shown for explanation of the procedure of a method for measuring pattern dependent jitter according to the first embodiment described above.

First, the data signal Dt having a predetermined N-bit length pattern synchronizing with the clock signal CK having a predetermined frequency outputted from the clock generating unit 21 is provided from the pattern generating unit 22 to the measuring object 1 (step S1).

Next, information of the waveforms in the same time domain of the data signal Dr to be measured outputted from the measuring object 1 and the clock signal CK outputted from the clock generating unit 21

are acquired by the waveform information acquiring unit 23 (step S2).

Further, averaging processing is carried out on the waveform acquired by the waveform information acquiring unit 23 by the averaging processing unit 24, and whereby random noise jitters are eliminated therefrom (step S3).

Next, the phase difference detecting unit 25 determines the phase differences $\Delta T(i)'$ between the clock signal CK' and the data signal Dr' to be measured, for one frame, for each bit of the data signal to be measured, based on the waveforms obtained due to the averaging processing by the averaging processing unit 24 (step S4).

Subsequently, the frequency band limiting processing unit 26 carries out a predetermined frequency band limiting processing on one frame of the phase difference information determined by the phase difference detecting unit 25 (step S5).

Next, the measured result outputting unit 27 determines the pattern dependent jitter of the measuring object 1, and outputs it as a measured result (step S6).

In this way, the jitter measuring apparatus 20 and measuring method according to the first embodiment measure pattern dependent jitter by acquiring waveform information in the same time domain of the data signal

Dr to be measured outputted from the measuring object 1 and the clock signal CK; removing the random noise jitter component by equalizing the waveform information; determining, for one frame, the per-bit phase difference of the clock signal CK' and the data signal Dr' to be measured from which the noise jitter has been removed; and carrying out predetermined frequency band limiting processing on this phase difference information.

10 Therefore, the jitter measuring apparatus 20 and measuring method according to the first embodiment can exactly measure only the pattern dependent jitter, which has been impossible in the eye-pattern observation of a prior art.

15 Further, the jitter measuring apparatus 20 and measuring method in accordance with the first embodiment can easily grasp the relation between the position of a data signal and pattern dependent jitter, which has been impossible in the eye-pattern observation of the prior art.

20 Note that, as a modified example of the jitter measuring apparatus 20 and measuring method according to the first embodiment, as shown by the broken line in FIG. 1, the case where the apparatus is configured such that the data signal Dt from the pattern generating unit 22 is directly inputted to the waveform information acquiring unit 23 as the data

signal Dr' to be measured, without being inputted to the measuring object 1 via the output terminal 20a, can be thought.

Namely, the jitter measuring apparatus 20 according to the modified example is applied to a case where the pattern dependent jitter of the data signal Dr to be measured outputted from the measuring object 1 is not measured, and due to the data signal Dt from the pattern generating unit 22 in the jitter measuring apparatus 20 being made to be the data signal Dr' to be measured, the pattern dependent jitter of the data signal Dr' to be measured is measured.

Because the jitter measuring apparatus 20 according to the modified example is a technique applied to the case where the pattern dependent jitter of the data signal Dr' to be measured is measured due to the data signal Dt from the pattern generating unit 22 in the jitter measuring apparatus 20 being made to be the data signal Dr' to be measured, namely, there is the merit that a traceability function as an internal standard can be provided therein.

(Second Embodiment)

The above description of the jitter measuring apparatus in accordance with the first embodiment is described with respect to the basic configuration of the present invention. However, next, a configuration example of a further concrete jitter measuring

apparatus as a second embodiment of the present invention will be described.

FIG. 6 is a block diagram showing a configuration as the second embodiment and a modified example thereof 5 of the jitter measuring apparatus according to the invention.

A jitter measuring apparatus 20' shown in FIG. 6 is an apparatus in which a light transmitter (an Electrical-Optical converter) which converts 10 an electric data signal into an optical data signal, and emits it, is made to serve as a measuring object 1.

The jitter measuring apparatus 20' provides the electric data signal Dt from the pattern generating 15 unit 22 via the output terminal 20a to the measuring object 1, and provides the clock signal CK from the clock generating unit 21 via the output terminal 20c to the measuring object 1.

In a case of this type of measuring object 1, 20 namely, the light transmitter (an Electrical-Optical converter) delays the clock signal CK at the inside thereof so as to be not affected with jitter of a data signal generally inputted, and carries out waveform shaping of the data signal Dt by using the delayed 25 clock signal, and emits an optical data signal Dp to be measured obtained due to intensity of light being modulated by the waveform-shaped signal.

Accordingly, even if pattern dependent jitter is included in the data signal Dt outputted from the pattern generating unit 22, the jitter component is made small enough to be ignored due to the above-
5 described waveform shaping processing in the measuring object 1, the pattern dependent jitter included in the data signal Dp to be measured outputted from the measuring object 1 can be considered as the jitter which arose at the measuring object 1 itself (mainly,
10 a modulating portion or an outputting portion).

The jitter measuring apparatus 20' receives the optical data signal Dp to be measured at an input terminal 20d, and converts the data signal Dp to be measured into the electric data signal Dr to be measured by an Optical-Electrical converter 31.

Note that, as will be described later, when the sampling oscilloscope 32 has a function that an optical signal is directly received, and is Optical-Electrical converted at the inside thereof, the Optical-Electrical converter 31 is omitted, and the optical data signal Dp to be measured can be directly inputted to the sampling oscilloscope 32.
20

In the jitter measuring apparatus 20', in place of the above-described waveform information acquiring unit 23 and averaging unit 24 in the first embodiment, the digital sampling oscilloscope 32 having a function of acquiring waveform information of a high-speed data
25

signal, and a function of averaging processing on the acquired waveform, is used.

The sampling oscilloscope 32 is configured so as to carry out sampling for the clock signal CK and the data signal Dr to be measured inputted, for example, as shown in FIGS. 7A and 7B, at a period T_s ($= K \cdot T_f + \Delta T_r$ or $= K \cdot T_f - \Delta T_r$) which is different by a slight time ΔT_r from a period $K \cdot T_f$ which is K times (K is an arbitrary integer, and denotes the case of $K = 1$ in FIG. 7) of a frame period T_f (given that a period of the clock signal CK is T_c , $N \cdot T_c$) of the data signal Dt, as shown in FIG. 7C.

As shown in FIGS. 7D and 7E, the sampling oscilloscope 32 determines the waveform information H_c and H_d of the clock signal CK and the data signal Dr to be measured due to the time resolution of ΔT_r .

The sampling oscilloscope 32 has an external trigger function in which acquisition of waveform information can be started from the timing which is synchronized with the level displacement timing of a signal inputted to an external trigger terminal (not showed) or which passes for an arbitrary time from the timing.

However, in a case of this type of sampling oscilloscope, a length of waveform (time range) which can be observed is determined by time resolution ΔT_r and a capacity of a memory for storing waveform

information, and in order to high-accurately detect a phase difference of the data signal Dr to be measured or the clock signal CK as described above, it is necessary to make time resolution ΔT_r small.

5 Accordingly, in this type of sampling oscilloscope, it is usually difficult to acquire or averaging-process all at once one frame of waveform information of the data signal Dr to be measured.

10 Then, here, the acquisition start timing (acquisition range) of the waveform information of the data signal Dr to be measured and the clock signal CK are shifted by Q bits.

15 Note that the shifted value Q may be a value less than or equal to the bit length of the waveform in which the waveform information can be acquired and averaged by small time resolution ΔT_r as described above, and greater than or equal to 1.

20 Shifting of the acquisition timing of the waveform information is achieved due to the frame synchronization signal S outputted from the pattern generating unit 22 being delayed as the unit of time ($Q \cdot T_c$) corresponding to the Q bit length by a delay unit 33, and due to the delayed frame synchronization signal S_d being inputted to the above-described external trigger terminal of the sampling oscilloscope 32.

25 On the other hand, the phase difference detecting

unit 25,

(1) receives the waveform information of the data signal Dr' to be measured and the clock signal CK' which have been acquired and averaged by the sampling oscilloscope 32;

(2) determines Q bits of phase differences $\Delta T(i)', \dots, \Delta T(i+Q-1)'$ these data signal Dr' to be measured and clock signal CK' ;

(3) increases the delay amount of the delay unit 33 by Q bits, and shifts the acquisition region of the waveform information of the sampling oscilloscope 32 by Q bits with respect to the data signal Dr' to be measured and the clock signal CK' ;

(4) in this state, repeats the operation of receiving the waveform information of the data signal Dr' to be measured and the clock signal CK' which have been acquired and averaged by the sampling oscilloscope 32, and determining the phase differences $\Delta T(i+Q)', \dots, \Delta T(i+2Q-1)'$ thereof; and

(5) in accordance therewith, determines phase differences $\Delta T(1)', \Delta T(2)', \dots, \Delta T(N)'$ of one frame in the same way as in the above description.

Information of the phase differences $\Delta T(1)', \Delta T(2)', \dots, \Delta T(N)'$ for each bit obtained in this way are outputted to the frequency band limiting processing unit 26 in the same way as in the above description, and frequency band limiting processing determined in

advance in accordance with a bit rate is applied thereto.

Then, the processed result is outputted to the measured result outputting unit 27, and the processed result is display-outputted, printed-out, or outputted to an external device, as the unit of time or UIpp units, by the measured result outputting unit 27, as pattern dependent jitter Jdp which the measuring object 1 generates with respect to the data signal Dt.

FIG. 8 is a flowchart shown for explanation of the procedure of a method for measuring pattern dependent jitter by using the sampling oscilloscope 32 according to the second embodiment described above.

First, the clock signal CK having a predetermined frequency outputted from the clock generating unit 21 and the data signal Dt having a predetermined N bit length pattern which is outputted from the generating unit 22 and is synchronized with the clock signal CK, are provided to the measuring object 1 (step S11).

Next, Q bits of the waveform information in the same time domain of the data signal Dr to be measured and the clock signal CK which have been emitted from the measuring object 1 and Optical-Electrical converted, are acquired by the sampling oscilloscope 32 (step S12).

Next, averaging processing is carried out on the acquired waveform by the sampling oscilloscope 32,

and whereby random noise jitters are eliminated
(step S13).

Subsequently, Q bits of phase differences $\Delta T(i)$ of
the clock signal CK' and the data signal Dr' to be
5 measured are determined by the phase difference
detecting unit 25 based on the waveforms obtained by
detecting unit 25 based on the waveforms obtained by
the averaging processing (step S14).

Hereinafter, due to the processings from step S12
to step S14 being repeatedly carried out N/Q times
10 while the waveform acquisition range is shifted by Q
bits, phase differences of all bits (one frame range)
are obtained (steps S15, S16).

Next, predetermined frequency band limiting
processing is carried out by the frequency band
15 limiting processing unit 26 for the one frame amount
information of the phase differences (step S17).

Then, the measured result is outputted to the
measured result outputting unit 27 as the pattern
dependent jitter of the measuring object 1 (step S18).

20 Note that, as described above, in a case where the
sampling oscilloscope 32 itself has a shifting function
in which the acquisition timing (acquisition range) of
waveform information is arbitrarily shifted, a delay
unit is not provided at the exterior, and the acquisi-
25 tion timing of waveform information may be shifted by
controlling the shifting function of the sampling
oscilloscope by the phase difference detecting unit 25.

Further, in a case, as well, in which the
a shifting function in which the output timing of the
frame synchronization signal S is provided at the
pattern generating unit 22 side, a delay unit is not
5 provided at the exterior, and the acquisition timing of
waveform information can be shifted in the same way as
in the above description by controlling the function
with the phase difference detecting unit 25.

Furthermore, in a case where the above-described
10 shifting functions are provided in both of the sampling
oscilloscope 32 and the pattern generating unit 22, the
acquisition timing of waveform information can be
shifted by controlling the both with the phase
difference detecting unit 25.

15 For example, when the shifting function at
the sampling oscilloscope 32 side can, in units of
one bit, shift a number of bits up to a number of bits
which is less than N (e.g., up to 16 bits) and the
shifting function at the pattern generating unit 22
20 side can shift in units of 16 bits, the following
processing is carried out: 16 bits are shifted
bit-by-bit in the shift function of the sampling
oscilloscope 32 side and the phase difference of each
bit is determined, and thereafter, the state returns to
25 the initial state, and after shifting of 16 bits is
carried out in the shifting function of the pattern
generating unit 22 side, 16 bits are again shifted

bit-by-bit in the shifting function of the sampling oscilloscope 32 side and the phase difference of each bit is determined.

Moreover, when the sampling oscilloscope 32 has
5 a function in which the phases of the two signals CK
and Dr to be inputted can be relatively varied, due to
the first level displacement timing of the data signal
Dr to be measured being synchronized with the level
displacement timing of the clock signal CK by
10 controlling the function by the phase difference
detecting unit 25, the initial phase difference $\Delta T(1)$
described above can be set to 0.

In this way, there is no need to carry out
subtracting correction due to the initial phase
15 difference $\Delta T(1)$ described above, and with respect to
the following bits (the bits from thereon), a time
difference of the level displacement timing of the
clock signal CK and the level displacement timing (code
varying timing) of the data signal Dr to be measured
20 can be used as a phase difference as it is.

Note that, as a modified example of the jitter
measuring apparatus 20' and measuring method according
to the second embodiment, as shown by the broken line
in FIG. 6, the case where the apparatus is configured
25 such that the data signal Dt from the pattern.
generating unit 22 is directly inputted to the sampling
oscilloscope 32 as the data signal Dr' to be measured

without being inputted to the measuring object 1 via the output terminal 20a, can be thought.

Namely, the jitter measuring apparatus 20' according to the modified example is applied to a case where the pattern dependent jitter of the data signal Dr to be measured outputted from the measuring object 1 is not measured, and the pattern dependent jitter of the data signal Dr' to be measured is measured due to the data signal Dt from the pattern generating unit 22 in the jitter measuring apparatus 20' being made to be the data signal Dr' to be measured.

Because the jitter measuring apparatus 20' according to such a modified example is a technique applied to the case where the pattern dependent jitter of the data signal Dr' to be measured is measured due to the data signal Dt from the pattern generating unit 22 in the jitter measuring apparatus 20' being made to be the data signal Dr to be measured, namely, there is the merit that a traceability function as an internal standard can be provided therein.

(Third Embodiment)

FIG. 9 is a block diagram showing a configuration as a third embodiment and a modified example thereof of the jitter measuring apparatus according to the invention.

In the above-described jitter measuring apparatus 20' shown in FIG. 6 according to the second embodiment,

the electric data signal Dt is provided to the measuring object 1, and waveform information is acquired due to the optical data signal Dp to be measured outputted from the measuring object 1 being converted into the electric data signal Dr to be measured.

However, in a jitter measuring apparatus 20" shown in FIG. 9 in accordance with the third embodiment, the data signal Dt is converted into the optical data signal Dt' by an Electrical-Optical converter 35, and is provided to the measuring object 1 such as, for example, an optical amplifier from an output terminal 20e, and waveform information is acquired by converting the optical data signal Dp to be measured emitted from the measuring object 1 into the electric data signal Dr to be measured at the photoelectric converter 31.

Note that, in the jitter measuring apparatus 20" of the third embodiment shown in FIG. 9, portions which are the same as those of the above-described jitter measuring apparatus 20' shown in FIG. 6 according to the second embodiment are denoted with the same reference numerals, and description thereof will be omitted.

Further, in this case as well, when the sampling oscilloscope 32 has a function in which an optical signal is directly received and Optical-Electrical converted at the inside thereof, the Optical-Electrical

converter 31 is omitted, and the optical data signal D_p to be measured can be directly inputted to the sampling oscilloscope 32.

Note that, as a modified example of the jitter measuring apparatus 20" and measuring method according to the third embodiment, as shown by the broken line in FIG. 9, the case where the apparatus is configured such that the data signal D_t from the pattern generating unit 22 is directly inputted to the sampling oscilloscope 32 as the data signal D_r' to be measured, without being inputted to the measuring object 1 via the Electrical-Optical converter 35 and the output terminal 20e, can be thought.

Namely, the jitter measuring apparatus 20" according to the modified example is applied to a case where the pattern dependent jitter of the data signal D_r to be measured outputted from the measuring object 1 is not measured, and the pattern dependent jitter of the data signal D_r' to be measured is measured due to the data signal D_t from the pattern generating unit 22 in the jitter measuring apparatus 20" being made to be the data signal D_r' to be measured.

Because the jitter measuring apparatus 20" according to the modified example is a technique applied to the case where the pattern dependent jitter of the data signal D_r' to be measured is measured due to the data signal D_t from the pattern generating

unit 22 in the jitter measuring apparatus 20" being made to be the data signal Dr to be measured, namely, there is the merit that a traceability function as an internal standard can be provided therein.

5 As described above, the jitter measuring apparatus and the measuring method of the present invention measure pattern dependent jitter by acquiring waveform information in the same time domain of a data signal to be measured and a clock signal; removing the random noise jitter component by averaging the waveform information; determining, for one frame, the per-bit phase difference of the clock signal and the data signal to be measured from which the random noise jitter has been removed; and carrying out predetermined frequency band limiting processing on this phase difference information.

10

15

Therefore, the jitter measuring apparatus and the measuring method of the present invention can exactly measure only the pattern dependent jitter, which has been impossible in the eye-pattern observation of the prior art, and can easily grasp the association between a position of data and the pattern dependent jitter.

20

Additional advantages and modifications will readily occur to those skilled in the art. Therefore, the invention in its broader aspects is not limited to the specific details and representative embodiments shown and described herein. Accordingly, various

25

modifications may be made without departing from the spirit or scope of the general inventive concept as defined by the appended claims and their equivalents.
